# Add-on Setup

This guide covers setting up the Google Workspace Add-on for development and testing.

## Prerequisites

- A Google Workspace account with access to Apps Script
- The backend deployed and accessible from the internet
- A `PUBLIC_TICKET_API_KEY` configured on the backend

## Step 1: Create Apps Script Project

1. Go to script.google.com
2. Click **New Project**
3. Rename the project to `KUCCPS IT Support Add-on`

## Step 2: Paste Code

1. Open `Code.gs` in the Apps Script editor

2. Paste the contents of `google-addon/Code.gs`
3. Open `appsscript.json` and paste the contents of `google-addon/appsscript.json`

# Step 3: Configure Script Properties

1. In the Apps Script IDE, click **Project Settings** (gear icon)
2. Scroll to **Script Properties**
3. Add the following properties:

| Property | Value | Description |
|---|---|---|
| `API_URL` | `http://localhost:5000/api` | Backend API URL (use ngrok/tunnel for local testing) |
| `BACKEND_API_KEY` | Your public API key | Authentication key |
| `SUPPORT_EMAIL` | `itsupport@kuccps.ac.ke` | Support email address |

# Step 4: Run Setup Function

Run `setupProductionProperties` from the Apps Script editor to populate properties if they are empty:

```
function setupProductionProperties() {
  const properties = PropertiesService.getScriptProperties();
  properties.setProperty('API_URL', 'https://api.example.ac.ke/api');
  properties.setProperty('BACKEND_API_KEY', 'your-api-key-here');
```

```
  properties.setProperty('SUPPORT_EMAIL', 'itsupport@kuccps.ac.ke');
}
```

## Step 5: Test Deployment

1. Click **Deploy > Test deployments**
2. Select **Install** to test as yourself
3. Open Gmail and look for the add-on icon in the compose window or email thread

## Step 6: Create Production Deployment

1. Click **Deploy > New deployment**
2. Select **Add-on** as the deployment type
3. Configure deployment settings
4. Click **Install** to install for your domain

## Local Testing with Tunnels

For local development, use a tunnel service like `ngrok` or `cloudflared` to expose your local backend:

```
# Using ngrok
ngrok http 5000

# Using cloudflared
```

```
cloudflared tunnel --url http://localhost:5000
```

Update `API_URL` in Apps Script properties to the tunnel URL.

> **Warning:** Do not use temporary tunnel URLs for production. Use a named Cloudflare Tunnel or official HTTPS domain.

# Debugging

- Use **View > Logs** in Apps Script to see console output.
- Use `Logger.log()` statements in `Code.gs` for debugging.
- Check backend logs for API request details.
